1. Review matroids M
   - independent sets $\mathcal{I}(M)$
   - flats $\mathcal{F}(M)$

2. Shellability

3. Augmented Bergman complex Δ_M

4. Two kinds of shellings of Δ_M and corollaries

1. Review matroids M

A matroid M of rank r on groundset $E = \{1, 2, \ldots, n\}$ abstracts vectors $v_1, v_2, \ldots, v_n$ spanning an r-dimensional vector space V over some field k

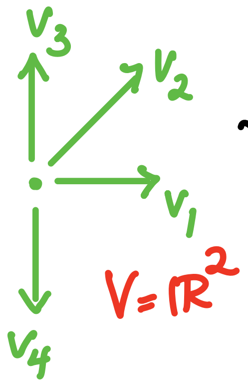
---

EXAMPLE

$n=4$

$k=\mathbb{R}$

$r=2$



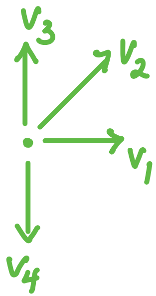
$\rightsquigarrow$ a (representable) matroid M, specified either by its independent sets $\mathcal{I}(M)$

or

flats $\mathcal{F}(M)$

independent sets

$$\mathcal{I}(M) \underset{\text{DEF'N}}{:=} \left\{ I \subseteq \{1,2,\dots,n\} : \begin{array}{l} \{v_i\}_{i \in I} \text{ are} \\ \text{linearly independent} \end{array} \right\}$$

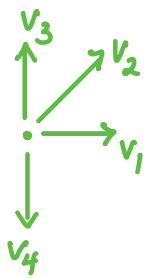


$$\rightsquigarrow \mathcal{I}(M) = \{ \emptyset, \; \begin{array}{l} 1, \\ 2, \\ 3, \\ 4 \end{array} \; \begin{array}{l} 12, \\ 13, \\ 14, \\ 23, \\ 24 \end{array} \}$$

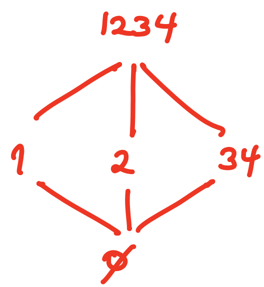
---

flats

$$\mathcal{F}(M) := \left\{ F \subseteq \{1,2,\dots,n\} : \begin{array}{l} \{v_i\}_{i \in F} = W \cap \{v_1, v_2, \dots, v_n\} \\ \text{for some subspace } W \text{ of } V \end{array} \right\}$$



$$\rightsquigarrow \mathcal{F}(M) = \{ \emptyset, 1, 2, 34, 1234 \}$$



the poset $\mathcal{F}(M)$ ordered via inclusion

$\mathcal{I}(M)$ satisfies these independent set axioms:

(I0) $\emptyset \in \mathcal{I}(M)$

(I1) $I \subseteq J$ and $J \in \mathcal{I}(M) \Rightarrow I \in \mathcal{I}(M)$

(I2) $I, J \in \mathcal{I}(M)$ and $\#I < \#J$
$\Rightarrow \exists\, j \in J \setminus I$ with $I \cup \{j\} \in \mathcal{I}(M)$

$\mathcal{F}(M)$ satisfies these flat axioms

(F0) $E = \{1, 2, \ldots, n\} \in \mathcal{F}(M)$

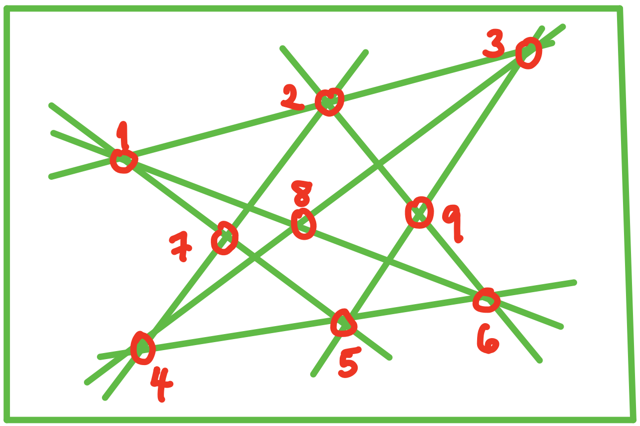
(F1) $F, G \in \mathcal{F}(M) \Rightarrow F \cap G \in \mathcal{F}(M)$

(F2) $F \in \mathcal{F}(M)$ and $i \in E \setminus F \Rightarrow$
$\exists!\, G \in \mathcal{F}(M)$ covering F with $i \in G$.

Not all matroids M are representable by vectors $v_1, v_2, \ldots, v_n$

EXAMPLE The non-Pappus matroid M on $E = \{1, 2, \ldots, 9\}$ of rank 3 has

$\mathcal{I}(M) = \{$all $I \subset \{1, 2, \ldots, 9\}$ with $\#I \leq 3$, except the collinear triples shown$\}$



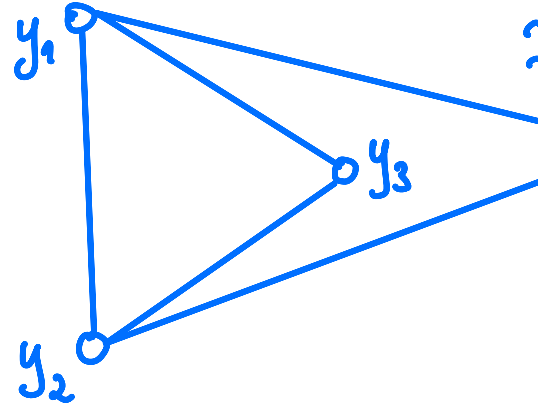
$789 \in \mathcal{I}(M)$ violates Pappus's Theorem

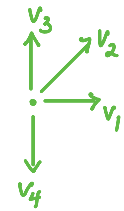
(I0) $\emptyset \in \mathcal{I}(M)$

(I1) $I \subseteq J$ and $J \in \mathcal{I}(M) \Rightarrow I \in \mathcal{I}(M)$

(I2) $I, J \in \mathcal{I}(M)$ and $\#I < \#J$
$\Rightarrow \exists j \in J \setminus I$ with $I \cup \{j\} \in \mathcal{I}(M)$

Axioms (I0), (I1) say $\mathcal{I}(M)$ is an **abstract simplicial complex** on vertices $\{y_1, y_2, \ldots, y_n\}$





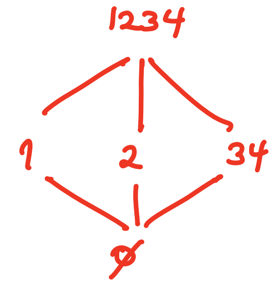
Axiom (I2) implies that all inclusion-maximal independent sets, called the **bases** $\mathcal{B}(M)$, have same cardinality r, called the **rank** $r(M)$.

In other words, $\mathcal{I}(M)$ is a **pure** simplicial complex of dimension $r(M)-1$.

(F0) $E = \{1,2,\dots,n\} \in \mathcal{F}(M)$

(F1) $F, G \in \mathcal{F}(M) \Rightarrow F \cap G \in \mathcal{F}(M)$

(F2) $F \in \mathcal{F}(M)$ and $i \in E \setminus F \Rightarrow$
$\exists!\ G \in \mathcal{F}(M)$ covering F with $i \in G$.



(F0), (F1) $\Rightarrow$ the poset $\mathcal{F}(M)$ is a lattice, with $F \wedge G = F \cap G$.

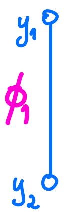
(F2) $\Rightarrow$ $\mathcal{F}(M)$ is actually a geometric lattice.

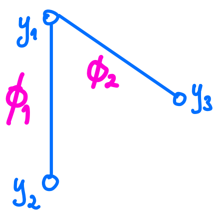
atomic + upper semimodular

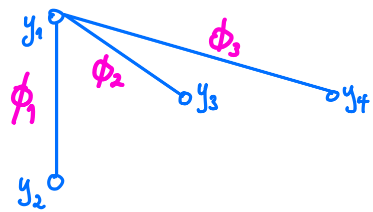
2. Shellability

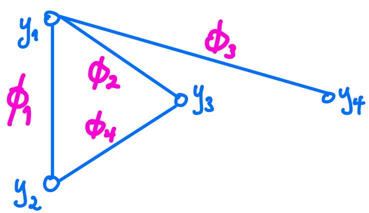
DEF'N: A pure $(r-1)$-dimensional simplicial complex Δ is shellable if we can order its facets $\phi_1, \phi_2, \ldots, \phi_t$ in a shelling order:

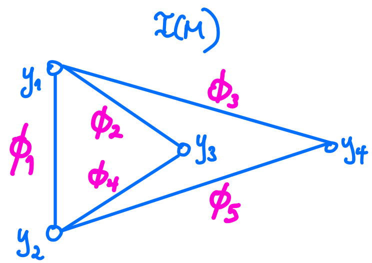
$\forall j \geq 2$, ϕ_j intersects the subcomplex generated by $\phi_1, \phi_2, \ldots, \phi_{j-1}$ in a pure $(r-2)$-dim'l subcomplex











Shelling determines the homotopy type of Δ

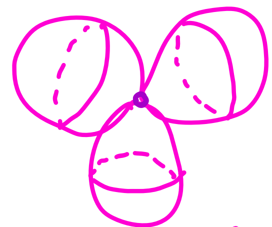
DEF'N: Call ϕ_j a homology facet in the shelling $\phi_1, \phi_2, \dots, \phi_t$ if ϕ_j intersects the subcomplex gen'd by $\phi_1, \phi_2, \dots, \phi_{j-1}$ in the entire boundary $\mathrm{Bd}\,\phi_j$

PROPOSITION: When Δ is pure d-dimensional and shellable,

then
$$\|\Delta\| \approx \underbrace{S^d \vee S^d \vee \dots \vee S^d}_{\beta\text{-fold 1-point wedge of } d\text{-spheres } S^d}$$

geometric realization of Δ

homotopy equivalent



$S^2 \vee S^2 \vee S^2$

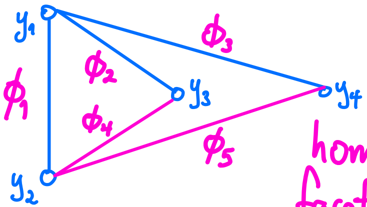
$d=2,\ \beta=3$

where $\beta :=$ # of homology facets ϕ_j in any shelling order

In fact, whenever Δ is shellable,

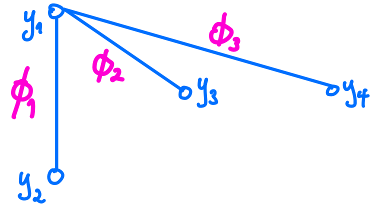
then $\Delta' := \Delta - \left\{ \begin{matrix} \text{all homology} \\ \text{facets } \phi_j \end{matrix} \right\}$ is contractible:

$\Delta = \mathcal{I}(M)$



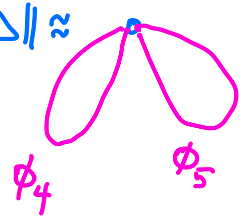
homology facets ϕ_4, ϕ_5

$\Delta' =$

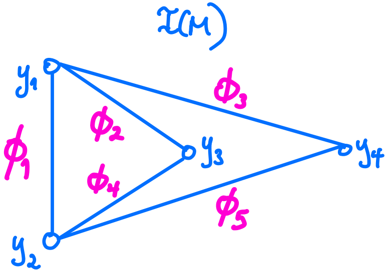


contract Δ' to a point

$\|\Delta\| \approx$



THEOREM (Provan–Billera 1980) For a matroid M, the independent set complex $\mathcal{I}(M)$ is shellable, via lexicographic order on the bases $\mathcal{B}(M)$.



$$\begin{array}{ccccccccc} \phi_1 & & \phi_2 & & \phi_3 & & \phi_4 & & \phi_5 \\ 12 & <_{lex} & 13 & <_{lex} & 14 & <_{lex} & 23 & <_{lex} & 24 \end{array}$$

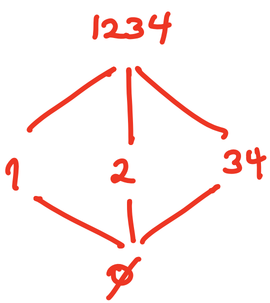
Furthermore, the number of homology facets is

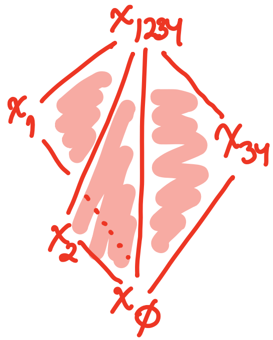
$$\beta = T_M(0,1) = \text{Tutte polynomial } T_M(x,y) \text{ evaluated at } x=0, y=1$$
$$= \#\text{ bases } B \in \mathcal{B}(M) \text{ of internal activity zero}$$

COROLLARY: $$\|\mathcal{I}(M)\| \simeq \underbrace{S^{r(M)-1} \vee \cdots \vee S^{r(M)-1}}_{T_M(0,1)\text{-fold wedge}}$$

The flats $\mathcal{F}(M)$ as a poset P gives us another simplicial complex, the order complex $\Delta P :=$ simplicial complex with vertex set $\{x_p\}_{p\in P}$ and ~~simplices~~/faces the totally ordered subsets $\{x_{p_1}, x_{p_2}, \dots, x_{p_\ell}\}$ if $p_1 < p_2 < \dots < p_\ell$ in P

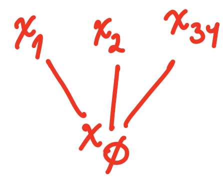
flat poset $\mathcal{F}(M) \xrightarrow{\text{order complex}} \Delta\mathcal{F}(M)$





contractible

$\mathrm{Cone}(\Delta_M) \overset{\mathrm{DEF}}{:=} \Delta(\mathcal{F}(M) - \{E\})$



contractible

Bergman complex $\Delta_M \overset{\mathrm{DEF}}{:=} \Delta(\mathcal{F}(M) - \{\emptyset, E\})$

$\mathbb{S}^0 \vee \mathbb{S}^0$

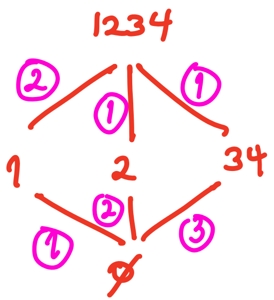
a 2-fold wedge of 0-spheres

THEOREM (Garsia 1980) For a matroid M, all three of $\left\{\begin{array}{l}\Delta\mathcal{F}(M)\\ \Delta(\mathcal{F}(M)-\{E\})\\ \Delta(\mathcal{F}(M)-\{\varnothing,E\}) =: \underline{\Delta}_M\end{array}\right.$

are shellable, via lexicographic order on the edge-label sequences on maximal chains $\varnothing \subset F_1 \subset F_2 \subset F_3 \subset \cdots \subset F_{r(M)-1} \subset E$ in $\mathcal{F}(M)$

edge-labels: $(\min F_1, \min(F_2 \setminus F_1), \min(F_3 \setminus F_2), \ldots, \min(E \setminus F_{r(M)-1}))$

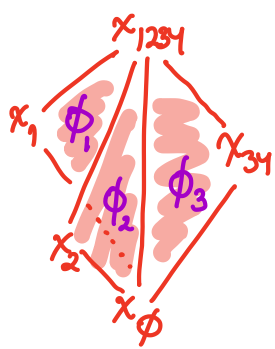
$\mathcal{F}(M)$



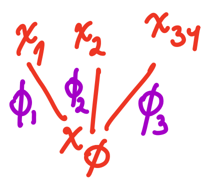
$(1,2) <_{lex} (2,1) <_{lex} (3,1)$

$\phi_1 \qquad \phi_2 \qquad \phi_3$

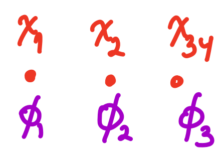
$\Delta\mathcal{F}(M)$



$\Delta(\mathcal{F}(M)-\{E\})$



$\Delta(\mathcal{F}(M)-\{\varnothing,E\})$



Furthermore, the number of homology facets is

$\beta = T_M(1,0)$ = Tutte polynomial $T_M(x,y)$ evaluated at $x=1, y=0$

= # bases $B \in \mathcal{B}(M)$ of external activity zero

COROLLARY: $\|\Delta(M)\| \simeq \underbrace{S^{r(M)-2} \vee \dots \vee S^{r(M)-2}}_{T_M(1,0)\text{-fold wedge}}$

Bergman complex

$\Delta_M := \Delta(\mathcal{F}(M) - \{\bar{\phi}, E\})$

3. Augmented Bergman complex Δ_M

In a monumental pair of 2020 papers, Braden-Huh-Matherne-Proudfoot-Wang introduced a hybrid.

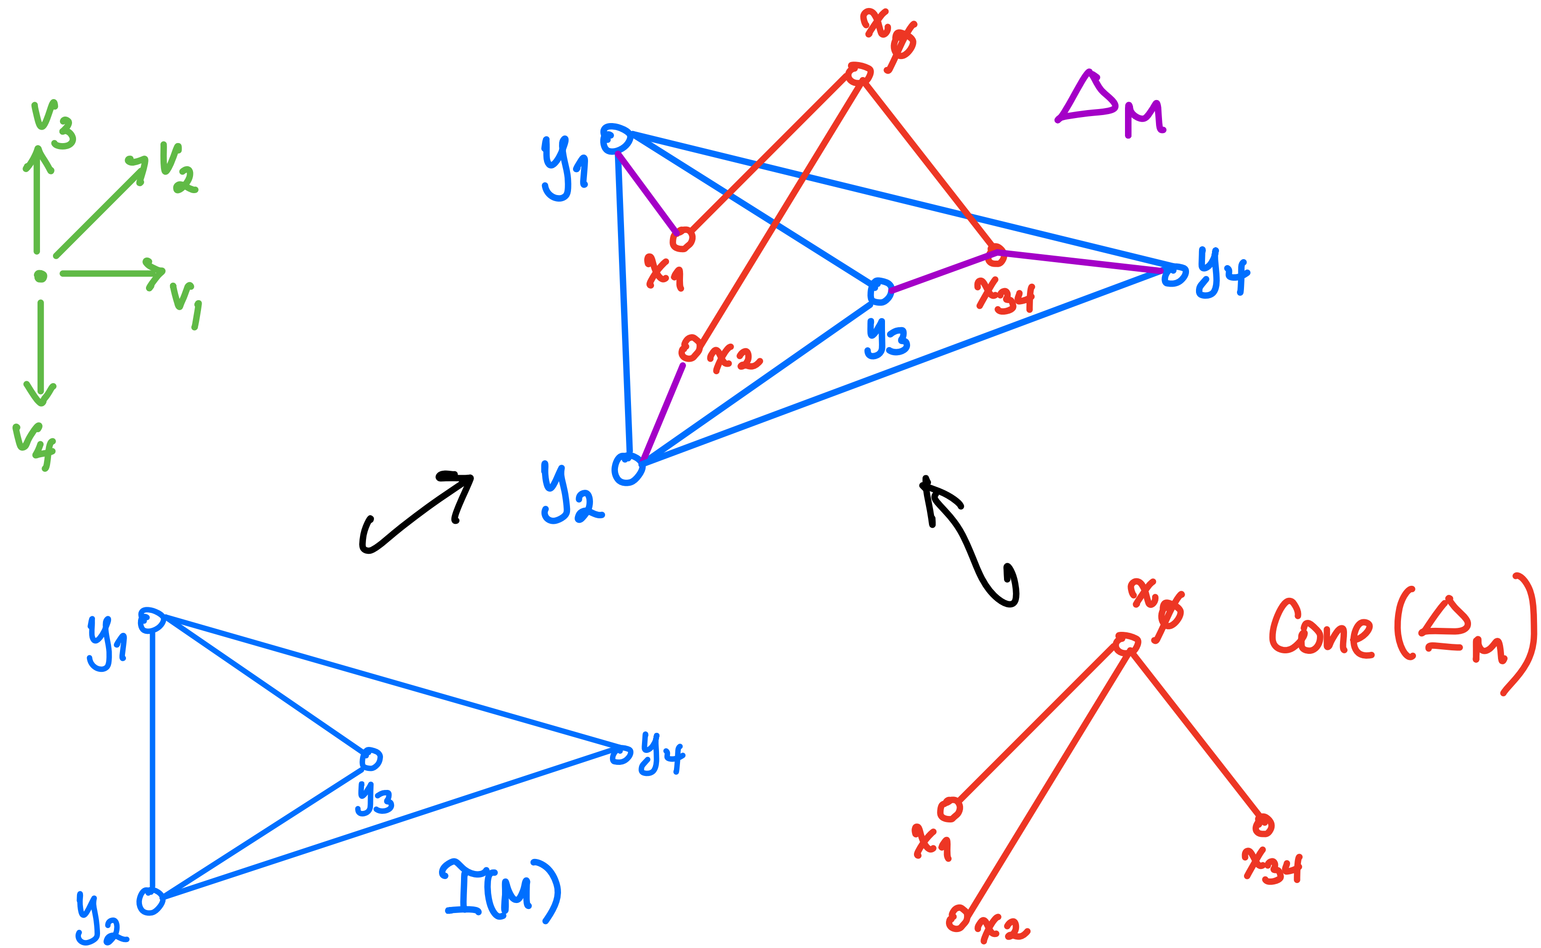
DEF'N: The augmented Bergman complex Δ_M

has vertex set $\{y_1, y_2, \ldots, y_n\} \cup \{x_F\}_{\emptyset \subseteq F \subsetneq E}$ proper flats $F \in \mathcal{F}(M)$

with simplices/faces $\{y_i\}_{i \in I} \cup \{x_{F_1}, x_{F_2}, \ldots, x_{F_\ell}\}$

when
- $I \in \mathcal{I}(M)$ is independent
- $F_1, F_2, \ldots, F_\ell$ are proper flats
- $I \subseteq F_1 \subset F_2 \subset \cdots \subset F_\ell \; (\neq E)$

Δ_M is pure of dimension $r(M)-1$, containing both $\mathcal{I}(M)$ and $\mathrm{Cone}(\Delta_M)$ as subcomplexes:



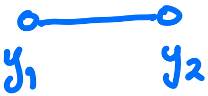
SPECIAL CASE : Boolean matroid M of rank n

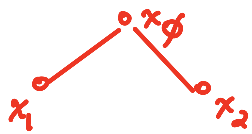
$\mathcal{I}(M)$
$= (n-1)$-simplex
$2^{\{1,2,\ldots,n\}}$

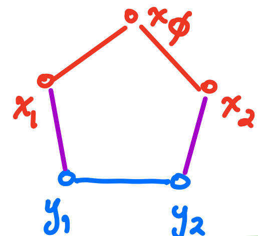
$\mathrm{Cone}(\Delta_M)$
$=$ barycentric subdivision of $(n-1)$-simplex

Δ_M
$=$ boundary of stellohedron

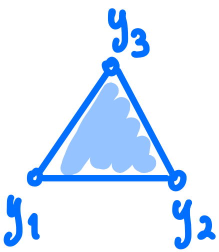
$n=2$

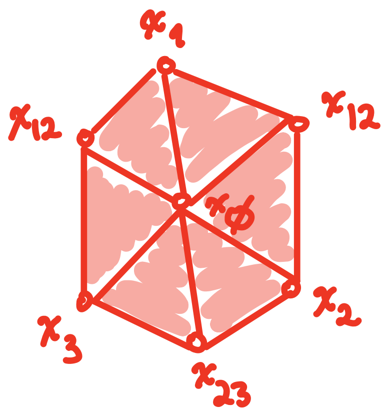


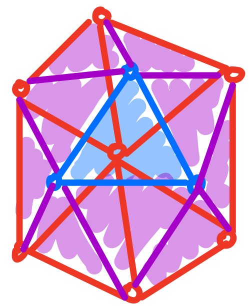




$n=3$







Why did BHMPW introduce Δ_M?

Its Stanley-Reisner ring has an amazing Artinian quotient by certain linear forms

$$CH(M) = \mathbb{R}[y_1,\dots,y_n, x_F]_{\substack{\text{flats} \\ F \subsetneq E}} \Bigg/ \left(\begin{array}{l} x_F x_G, \quad F \not\subseteq G, G \not\subseteq F \\ y_i x_F, \quad i \notin F, \\ y_i - \sum_{i \notin F} x_F, \quad i = 1,2,\dots,n \end{array} \right)$$

= augmented Chow ring of M

in which the $y_1,\dots,y_n$ generate a subalgebra $H(M)$

= graded Möbius algebra of M

with a crucial $H(M)$-submodule $IH(M)$

= intersection cohomology of M

and remarkable properties...

- $H(M) \hookrightarrow IH(M) \hookrightarrow CH(M)$ these satisfy Kähler package
- Hilbert series for $H(M)$ interprets rank sizes W_k of $\mathcal{F}(M)$
  and Kähler package for $IH(M)$ $\Rightarrow$ Dowling-Wilson's Top Heavy Conj. (1974)
- Hilbert series for $IH(M)$ interprets Z-polynomial for M
  and Kähler package for $IH(M)$ $\Rightarrow$ unimodality for Z
- Hilbert series for $IH(M)/(y_1,\dots,y_n)IH(M)$
  interprets Kazhdan-Lustzig polynomial for M
  $\Rightarrow$ nonnegativity of K-L polynomial!

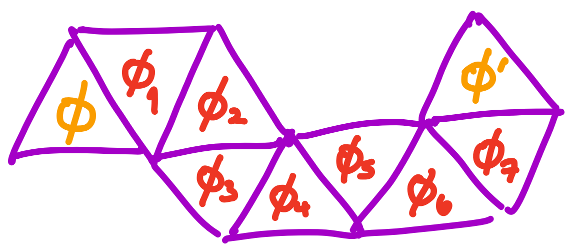
They used this weaker property of Δ_M than shellabity:

PROPOSITION (BHMPW 2020): For any matroid M,

Δ_M is gallery-connected,

that is, any two facets ϕ, ϕ' are connected by a gallery of facets $\phi = \phi_0, \phi_1, \phi_2, \ldots, \phi_{t-1}, \phi_t = \phi'$

with each $\phi_i \cap \phi_{i+1}$ of dimension $r(M)-2$ (= codimension 1)



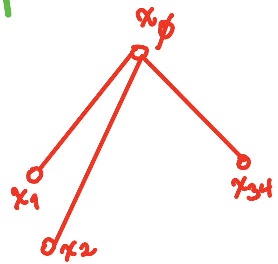
4. Two kinds of shellings of Δ_M and corollaries

THEOREM (UMN REU 2021) For any matroid M, the augmented Bergman complex has two families of shellings:

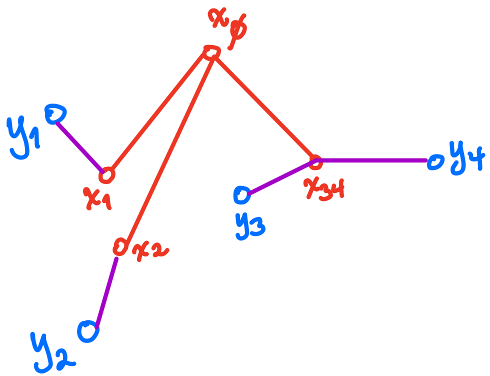
(i) some that shell the facets of $\mathrm{Cone}(\underline{\Delta}_M)$ first, and facets of $\mathcal{I}(M)$ last.

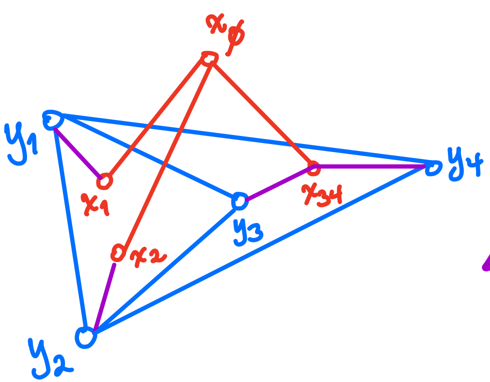
(ii) some that shell the facets of $\mathcal{I}(M)$ first, and facets of $\mathrm{Cone}(\underline{\Delta}_M)$ last.

Type (i) shellings



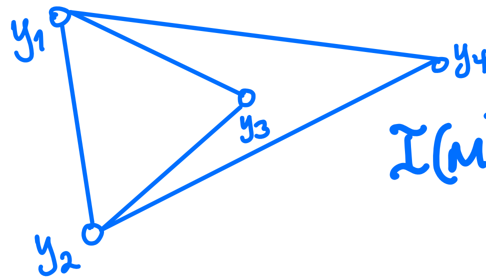
Cone(Δ_M)



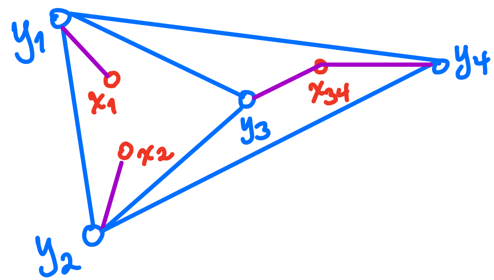


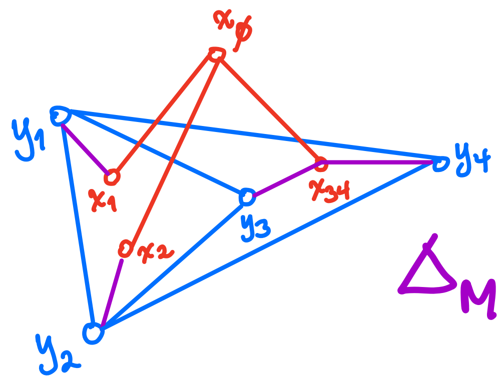
Δ_M

Type (ii) shellings



$\mathcal{I}(M)$





Δ_M

COROLLARY (UMN REU 2021): The augmented Bergman complex Δ_M has $\|\Delta_M\| \approx \underbrace{S^{r(M)-1} \vee \cdots \vee S^{r(M)-1}}_{\beta\text{-fold wedge}}$

where β has two expressions:

(i) $\beta = T_M(1,1) = \#\mathcal{B}(M)$
because the homology facets in type (i) shellings are $\{y_i\}_{i \in B}$ indexed by bases B of M.

(ii) $\beta = \sum_{\text{flats } F \in \mathcal{F}(M)} T_{M|_F}(0,1)\, T_{M/F}(1,0)$
counting type (ii) shelling homology facets.

REMARK: The equality

$$T_M(1,1) = \sum_{\text{flats } F} T_{M|_F}(0,1)\, T_{M/F}(1,0)$$

appeared in work of Étienne-Las Vergnas 1998,

rediscovered in Kook-R.-Stanton 2000,

and is a specialization of a convolution formula

$$T_M(x,y) = \sum_{\text{flats } F} T_{M|_F}(0,y)\, T_{M/F}(x,0)$$

for Tutte polynomials.

The type (i) shellings show contractibility of

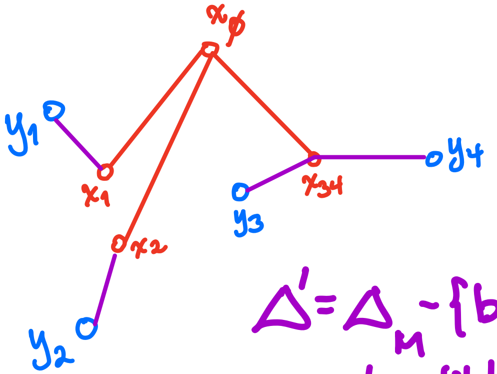
$$\Delta' = \Delta_M - \{\text{facets } \{y_i\}_{i\in B} : \text{bases } B \in \mathcal{B}(M)\}$$

Since matroid automorphisms set-wise stabilize the collection of basis facets, one can conclude:

COROLLARY: The group $\mathrm{Aut}(M)$ acts on $H_{r(M)-1}(\Delta_M, \mathbb{Z})$ as a signed permutation representation, same as on $C_{r(M)-1}(\mathcal{I}(M), \mathbb{Z})$:

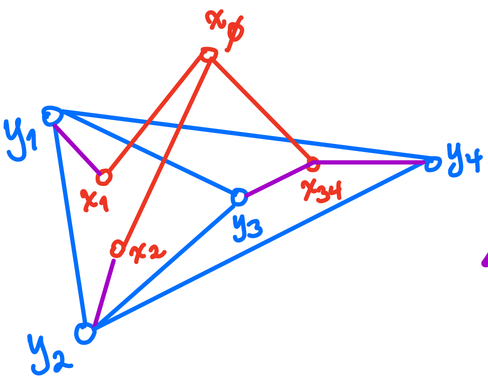
$$\sigma([b_1, b_2, \ldots, b_r]) = [b_{\sigma(1)}, \ldots, b_{\sigma(r)}] \text{ for bases } B = \{b_1, \ldots, b_r\} \in \mathcal{B}(M)$$

oriented simplex

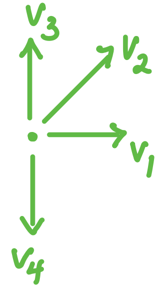


$$\Delta' = \Delta_M - \{\text{bases}\}$$

is contractible

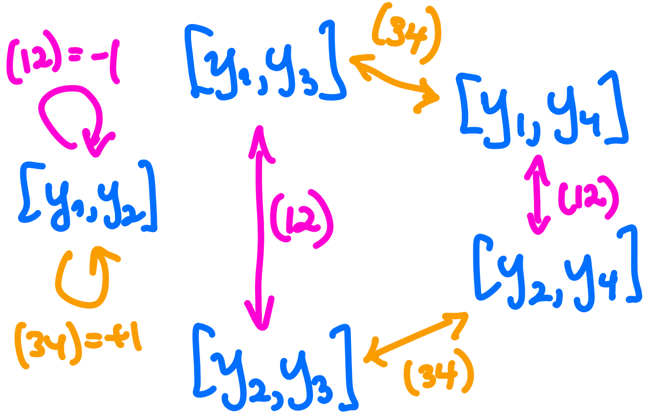


Δ_M



$$\mathrm{Aut}(M) = \{e, (12), (34), (12)(34)\}$$

$$H_1(\Delta_M) = \mathbb{Z}^5$$



REMARK: Neither $\mathcal{I}_M$ nor Δ_M have simple descriptions for their homology representations in general.

Notable special cases:

matroid M	$H_{r(M)-1}(\mathcal{I}_M)$	$H_{r(M)-2}(\Delta_M)$
Boolean	trivial rep of S_n	sign rep of S_n
q-Boolean = $\mathbb{F}_q$-vector space	known virtually, not so explicit	Steinberg rep of $GL_n(\mathbb{F}_q)$
braid arrangement = complete graphic	an S_n-rep that restricts nicely to S_{n-1} (Kook 1996)	Lie rep of S_n

Thanks
for
your
attention!

(Extra pages)

REMARK: Can generalize Aut(M)-rep description to arbitrary closure operators $2^E \xrightarrow{f} 2^E$

defining indep. sets I : $f(I \setminus \{i\}) \subsetneq f(I) \;\forall i \in I$

bases B : B indep. and $f(B) = E$

flats F : $f(F) = F$

and augmented Bergman complex Δ_f

with vertices $\{y_1, \ldots, y_n\} \cup \{x_F\}_{\text{proper flats } F \subsetneq E}$

simplices $\{y_i\}_{i \in I} \cup \{x_{F_1}, \ldots, x_{F_\ell}\}$

with
- I indep.
- $F_1, \ldots, F_\ell$ flats
- $I \subseteq F_1 \subset \ldots \subset F_\ell$

$\mathcal{I}(f)$, $\underline{\Delta}_f$, Δ_f are not shellable in general.

Nevertheless:

THEOREM (UMN REU 2021) $\|\Delta_f\| \simeq \bigvee_{\text{bases } B} \mathbb{S}^{\#B-1}$

and $\mathrm{Aut}(M)$ acts on $H_\bullet(\Delta_f)$ as a signed permutation rep on oriented chains $[b_1, b_2, \ldots, b_r]$ indexed by bases $B = \{b_1, \ldots, b_r\}$.

Again $\Delta' := \Delta_f - \{ \{y_i\}_{i \in B} : B \text{ a basis} \}$ is contractible.
