GAUGE THEORIES ON NONCOMMUTATIVE EUCLIDEAN SPACES

ALBERT SCHWARZ

Department of Mathematics, University of California, Davis, CA 95616

We consider gauge theories on noncommutative euclidean space . In particular, we discuss the structure of gauge group following standard mathematical definitions and using the ideas of Ref. 2.

The goal of this note is to consider gauge theories on noncommutative euclidean space and, in particular, to study the structure of gauge group. This group was analyzed by J. Harvey in recent paper.¹ It was suggested in this paper that the definition of the gauge group "presumably can be derived from the first principles." We would like to analyze the relation of Harvey's definition to the standard mathematical definition using as a starting point some ideas of Ref. 2, in particular, the idea that the theory becomes more transparent if along with simple modules A^n we consider more complicated modules \mathcal{F}_{rn} . (The central point of Ref. 2 — the suggestion to work with unitized algebras — is mentioned only in passing at the very end.)

Mathematical definition of a gauge field is based on a notion of connection on a module E over associative algebra A. There exist different versions of this notion (see Ref. 3 for details, Ref. 4 for more general treatment). Our consideration does not depend on these subtleties. We can use, for example, the very first definition;⁵ in this definition linear operators $\nabla_{1,...}, \nabla_d$ specify a connection on right A-module E if they satisfy Leibniz rule:

$$\nabla_{\alpha}(ea) = (\nabla_{\alpha}e) \cdot a + e\partial_{\alpha}a$$

where $\partial_1, ..., \partial_d$ are derivations on $A, e \in E, a \in A$. One assumes that these derivations (i.e. infinitesimal automorphisms) constitute a basis of a Lie algebra. By definition a gauge field is a unitary connection (i.e. ∇_{α} should be anti-Hermitian operators).

It is supposed usually that A is a unital Banach algebra over \mathbb{C} and E is a Hilbert A-module (i.e. E is equipped with A-valued Hermitian inner product \langle , \rangle ; then the condition of unitarity of connection takes the form

$$\langle \nabla_{\alpha} a, b \rangle + \langle a, \nabla_{\alpha} b \rangle = \partial_{\alpha} \langle a, b \rangle.$$

(By definition a Banach algebra is an associative algebra with a norm and an involution obeying natural conditions. The vector space A^n of column vectors with entries from A, considered as a right A-module, can be equipped with A-valued Hermitian inner product $a_1^+b_1 + \ldots + a_n^+b_n$. Hence all projective A-modules, i.e. direct summands in A^n , can be considered as Hilbert modules.)

For every unital Banach algebra A we can construct a group U(A) consisting of unitary elements of A. The topology of this group and of groups $U_n(A) = U(\operatorname{Mat}_n(A))$ is closely related to the K-theory of A, namely,

$$K_i(A) = \pi_{i-1}(U_\infty(A)),$$

where $U_{\infty}(A) = \bigcup U_n(A)$ is a union (or more precisely direct limit) of groups $U_n(A)$. (This is one of possible definitions of K-groups.) Notice, that

$$\pi_i(U_\infty(A)) = \pi_{i+2}(U_\infty(A))\,,$$

(Bott periodicity theorem) for $i \ge 0$; using this periodicity we can define groups $\pi_i(U_{\infty}(A))$ for negative *i*.

The definitions and results that we formulated for Banach algebras can be applied also to more general algebras, equipped with antilinear involution.

In the definition of connection, we have used, the role of gauge transformations is played by unitary endomorphisms of E (unitary A-linear maps of Einto itself). This follows from the fact that for every unitary endomorphism φ the correspondence $\nabla_{\alpha} \to \nabla' = \varphi \nabla_{\alpha} \varphi^{-1}$ transforms a unitary connection ∇_{α} into a unitary connection ∇' ; corresponding curvatures are related in standard way: $F'_{\alpha\beta} = \varphi F_{\alpha\beta} \varphi^{-1}$. Considering the curvature of unitary connection as a field strength of a gauge field we obtain that all reasonable action functionals are invariant with respect to unitary endomorphisms. It is possible to consider the group of unitary endomorphisms $U(\operatorname{End}_A E)$ (the group of unitary elements of endomorphism algebra $\operatorname{End}_A E$) as a gauge group. If $E = A^1$ (U(1)-gauge field in the terminology of physicists) this group is isomorphic to U(A) and in the case of $E = A^n$ (the case of U(n)-gauge fields), it is isomorphic to $U_n(A) = U(\operatorname{Mat}_n(A))$. (We use the notation $\operatorname{Mat}_n(A)$ for the algebra of $n \times n$ matrices with entries from A. The endomorphisms of A^n , considered as a right module, can be identified with elements of $Mat_n(A)$ acting on A^n from the left.) It is important to notice that usually physicists work with a little bit different definition of gauge field, that is equivalent to the above definition restricted to the modules $E = A^n$ (free modules).

The above consideration can be applied also to non-unital algebras; the only essential difference is that the elements of $Mat_n(A)$ don't exhaust in this case all endomorphisms of A^n (the modules A^n cannot be considered as free

modules). The algebra M(A) of endomorphisms of A^1 is called multiplier algebra of A; using this definition one can represent endomorphisms of A^n as matrices with entries from M(A). We see that $U(\operatorname{End}_A A^n) = U(\operatorname{Mat}_n(M(A)))$.

As we have seen one can consider $U(\operatorname{End}_A E)$ as a gauge group. This means that we can identify two gauge fields connected by gauge transformation and use the integration over the quotient space \mathcal{C}/G , where $G = U(\operatorname{End}_A E)$, to quantize the gauge theory. (Here \mathcal{C} stands for the space of all gauge fields.) However, sometimes it is more convenient to introduce a stronger notion of gauge equivalence replacing $G = U(\operatorname{End}_A E)$ with its subgroup $G' \subset G$. As long as G/G' is compact we can use \mathcal{C}/G' instead of \mathcal{C}/G in the quantization procedure. However, if G' acts freely on \mathcal{C} it is more convenient to work with \mathcal{C}/G' .(This space is non-singular and its homotopy groups can be calculated in terms of homotopy groups of G'.)

For example, if we work with ordinary U(n)-gauge theory on compact manifold X (i.e. A = C(X) is a commutative algebra of functions on X) and $E = A^n$ is a trivial Hermitian vector bundle then $G = U(\text{End}_A E)$ consists of functions on X taking values in unitary matrices. In this case it is more convenient to consider as a gauge group the subgroup G' of G consisting of functions $\varphi \in G$ obeying $\varphi(x_0) = 1$ for a fixed point x_0 of X. The quotient group G/G' can be identified with the group of global gauge transformations. Notice that the separation of gauge transformations (that we use to define gauge classes) and global symmetry transformations is not physical in this case (it depends on the choice of x_0 .) However, sometimes the reduction of G to G' is prompted not only by mathematical convenience, but also by physical considerations. (It can happen, that it is necessary to consider observables that are G'-invariant, but not G-invariant.)

In particular, if we consider ordinary U(n)-gauge theory on \mathbb{R}^d , the action functional is invariant with respect to gauge transformations corresponding to U(n)-valued functions g(x), that have a limit as $x \to \infty$. However, it is reasonable to consider as a gauge group a smaller group G' imposing a condition $\lim_{x\to\infty} g(x) = 1$. (This means that we exclude global gauge transformations.)

The idea that one can modify the notion of gauge group without changing physics is reinforced by obvious remark that we can impose conditions partially removing gauge freedom (i.e. making the gauge group smaller).

Let consider now gauge theories on noncommutative euclidean space \mathbb{R}^d following the ideas of Ref. 2.

In this case we can work with various algebras corresponding to different behavior of gauge fields at infinity. Let us start with a (non-unital) algebra $A = S(\mathbb{R}^d_{\theta})$ of Schwartz functions on \mathbb{R}^d equipped with a star-product. Every connection on A^n has the form

$$\nabla_{\mu} = \partial_{\mu} + a_{\mu} \tag{1}$$

where a_{μ} is an $n \times n$ matrix with entries the multiplier algebra $M(A) = M(S(\mathbb{R}^d_{\theta}))$. One can consider the multiplier algebra as an algebra of generalized functions (distributions) with the multiplication defined as a star-product. In the case $\theta = 0$ the algebra M(A) consists of smooth functions, having derivatives with at most polynomial growth at infinity. For nonvanishing θ the description of M(A) is more complicated, see Ref. 6–8. This algebra essentially depends on the choice of θ . One can prove that for nondegenerate θ a continuous functional on Schwartz space $S(\mathbb{R})^d$ (a distribution) specifies an element of $M(A) = M(S(\mathbb{R}^d_{\theta}))$ if at infinity (i.e. in the complement to a compact set) it can be represented by a smooth function with all derivatives bounded by polynomials of the same degree.⁸ However, there exist multipliers that do not belong to this class.⁸

Notice, that we worked with right modules; then multipliers are realized by means of multiplication from the left. In the case of left modules multipliers act from the right. There exists an interesting algebra consisting of distributions that can be considered as left and right multipliers at the same time.⁶⁻⁸

Considering a_{μ} as a gauge field we can say that our gauge fields not necessarily decrease at infinity (they can even grow, but at most polynomially). Therefore we should impose an additional condition that gauge fields at hand have finite euclidean action (or finite energy). In the ideology of functional integral this condition follows from the fact the contribution of fields with infinite action vanishes. Notice that instead of the algebra $A = S(\mathbb{R}^d_{\theta})$ we can work, for example, with algebra of functions on \mathbb{R}^d that have derivatives of all orders and all these derivatives tend to zero at infinity (the multiplication is again defined as a star-product). This algebra is bigger, it has less connections (gauge fields are bounded in this case). However, this makes no difference: gauge fields having finite action are the same (if we impose some mild regularity conditions).

The condition of finiteness is a complicated non-linear condition. In the case when the dimension of the space is at least 4 we replace it with a condition that the gauge field is gauge trivial at infinity. We say that a connection on $A^n = (S(\mathbb{R}^d_{\theta}))^n$ is gauge trivial at infinity if it can be represented in the form

$$\nabla_{\mu} = T \circ \partial_{\mu} \circ S + (1 - TS) \circ \partial_{\mu} + \sigma_{\mu} \tag{2}$$

where $T, S \in \text{End}_A(A^n)$ are operators obeying $1 - TS = \Pi \in A, 1 - ST = \Pi' \in A$ and σ_{μ} is small at infinity in appropriate sense. We will always assume that

T belongs to $H\Gamma_1^{m,m_0}$, then there exists such $S \in H\Gamma_1^{-m,-m_0}$ that $1-TS \in A$, $1-ST \in A$. (See Refs. 9, 2 or Appendix for the definition of the class of hypoelliptic symbols $H\Gamma_{\rho}^{m,m_0}$ and for the definition of the class Γ_{ρ}^m ; roughly speaking $a \in \Gamma_{\rho}^m$ if $||a|| \leq \text{const } ||x||^m$ at infinity and $T \in H\Gamma_{\rho}^{m,m_0}$ if at infinity $T \in \Gamma_{\rho}^m$ and $T^{-1} \in \Gamma_{\rho}^{-m_0}$.) We will make precise the statement that σ_{μ} is small at infinity requiring that $\sigma_{\mu} \in \Gamma$ where Γ stands for the union of Γ_1^m with m < -1 (this means that σ_{μ} tends to zero faster than $||x||^{-1}$, i.e. faster than the first term in (2)). Let us denote by $\mathcal{C}(T)$ the class of connections that can be represented in the form (2) with fixed T and $\sigma_{\mu} \in \Gamma$. Considering $T \in H\Gamma_1^{m,m_0}$ as a matrix valued function on \mathbb{R}^d we obtain an element of $\pi_{d-1}(GL(n)) = \pi_{d-1}(U(n))$ as a homotopy class of the map of large sphere $S^{d-1} \subset \mathbb{R}^d$. The class $H\Gamma_1^{m,m_0}$ consists of components labeled by elements of $\pi_{d-1}(U(n))$. Let us fix an element T_k in every component of $H\Gamma_1^{0,0}$ and define $\mathcal{C}^{(k)}$ as $\mathcal{C}(T_k)$.

If T and T_k determine the same element of $\pi_{d-1}(U(n))$ one can prove that a gauge field (unitary connection) belonging to $\mathbb{C}(T)$ is gauge equivalent to a gauge field from $\mathbb{C}^{(k)} = \mathbb{C}(T_k)$ (i.e. these two gauge fields are related by unitary endomorphism). Moreover, in the case $\theta \neq 0$ this statement remains correct if we impose weaker condition that T and T_k determine the same element of stable homotopy group $\pi_{d-1}(U(\infty))$ (we will prove this statement below for the case of nondegenerate θ).

Working with gauge fields (unitary connections) it is convenient to replace (2) by an explicitly unitary expression

$$\nabla_{\mu} = T \circ \partial_{\mu} \circ T^{+} + \Pi \circ \partial_{\mu} \circ \Pi + \rho_{\mu} \tag{3}$$

where $T \in H\Gamma_1^{0,0}$, $\Pi = 1 - TT^+ \in A$, $\Pi' = 1 - T^+T \in A$, $\rho_{\mu} = \rho_{\mu}^+ \in \Gamma$. It is easy to check that every unitary connection belonging to $\mathcal{C}(T)$ where $T \in H\Gamma_1^{0,0}$ can be represented in the form (3). Notice, that in the case of nondegenerate θ we can consider elements of $\operatorname{Mat}_n(M(A))$ as pseudodifferential operators acting on $S(\mathbb{R}^m)$ where d = 2p. The topological class of T can be considered as index of corresponding pseudodifferential operator \widehat{T} . Without loss of generality we can assume that either $T^+T = 1$ (i.e. $\operatorname{Ker} \widehat{T} = 0$) or $TT^+ = 1$ (i.e. $\operatorname{Ker} \widehat{T}^+ = 0$).

We conjecture that calculating correlation functions we can do functional integral over fields that are gauge trivial at infinity. In very vague way one can say that "almost all" (but not necessarily all) fields having finite action are gauge trivial at infinity. (One can say that the finiteness of action implies gauge triviality for fields obeying some regularity conditions at infinity.Some results of this kind can be derived in commutative case from Uhlenbeck theorem.¹⁰)

It is convenient to modify the definition of gauge triviality at infinity in the following way: we say that the gauge field belongs to the class \mathcal{C}_m if Tin (3) belongs to $H\Gamma_1^{0,0}$ and ρ_{μ} belongs to Γ^m where Γ^m stands for the union of $\Gamma_1^{m'}$ with m' < m. We always assume that $m \leq -1$; under this assumption $\mathcal{C}_m \subset \mathcal{C}_{-1}$, i.e. a gauge field of the class \mathcal{C}_m is gauge trivial at infinity. It easy to check that the euclidean action of a gauge field from \mathcal{C}_m is finite if $m \leq 1 - \frac{d}{2}$. (Here d stands for the dimension of noncommutative euclidean space.)

Let us consider for definiteness the case d = 4. Noticing that $\pi_3(U(n)) = \mathbb{Z}$ we obtain that $H\Gamma_1^{0,0}$ consists of countable number of components labeled by an integer. Let us fix one operator T_k in every component and define \mathcal{C}_m^k as a set of gauge fields of the form (3) with $T = T_k$ and $\rho_\mu \in \Gamma^m = \bigcup_{m' < m} \Gamma_1^{m'}$. Every gauge field $\nabla_\mu \in \mathcal{C}_m$ is gauge equivalent to a gauge field from $\mathcal{C}'_m = \bigcup_{k \in \mathbb{Z}} \mathcal{C}_m^k$. (Recall that we consider the group of unitary endomorphisms $U(\operatorname{Mat}_n(M(A)))$ as a gauge group.) We see that we can restrict ourselves to the gauge fields from \mathcal{C}'_m . The gauge group becomes smaller after this restriction.

Similar statements are correct in any dimension. There are some complications related to the fact that in general the group $\pi_{d-1}(U(n))$ does not coincide with stable homotopy group $\pi_{d-1}(U(\infty)) = \pi_{d-1}(U_{\infty}(\mathbb{C}))$. However, in noncommutative case $(\theta \neq 0)$ the sets \mathcal{C}_m^k and \mathcal{C}_m^l defined by means T_k and T_l correspondingly are related by gauge transformation if T_k and T_l determine the same element of $\pi_{d-1}(U(\infty))$. (A proof for nondegenerate θ is given below.)This means that for odd d we need only one T, and for even d we should take $\mathcal{C}'_m = \bigcup_{r \in \mathbb{Z}} \mathcal{C}_m^r$ where the index r labels elements of $\pi_{d-1}(U(\infty)) = \mathbb{Z}$.

It is easy to check that a unitary endomorphism $\varphi = 1 + \tau$, where τ is a matrix with entries from Γ^{m+1} transforms C'_m into itself. It is convenient to consider the group $G = G^{(m+1)}$ consisting of endomorphisms of such a kind as residual gauge group, that remains when we restrict ourselves to the gauge fields from $\mathcal{C}' = \mathcal{C}'_m$. (We omit the index m in topological considerations, because homotopy groups of G and \mathcal{C}' don't depend on m.) It is easy to describe the topology of the group G. If θ is nondegenerate then $\pi_i(G) = \pi_i(U_\infty(\mathbb{C}))$; this homotopy group vanishes for odd i and is isomorphic to \mathbb{Z} for even i(Bott periodicity theorem). This statement becomes almost obvious if we take into account that the group G lies between $U_\infty(\mathbb{C})$ and the group \mathcal{K} of unitary transformations of the form $1 + \tau$ where τ is a compact operator. (See Refs. 11–13 for the analysis of topological properties of different spaces of operators in infinite-dimensional case.)

If $\theta = 0$ it is easy to check that $\pi_i(G) = \pi_{i+d}(U(n))$. If θ is degenerate, but $\theta \neq 0$ we have for even d the same answer as for the case of non-degenerate θ ; for

odd d we obtain that $\pi_i(G) = \pi_{i+d+1}(U_{\infty}(\mathbb{C}))$ (i.e. $\pi_{2k}(G) = 0, \pi_{2k+1}(G) = \mathbb{Z}$). The calculations for degenerate θ are based on the remark that in this case an element of G can be considered as a map of $S^{d-\operatorname{rank}\theta}$ into \mathcal{K} . (If θ is degenerate, but not equal to zero, we can assume that the first $d-\operatorname{rank}\theta$ coordinates commute with all coordinates and the last rank θ coordinates obey canonical commutation relations. Considering the first coordinates as parameters we obtain that an element of G can be regarded as a map of $\mathbb{R}^{d-\operatorname{rank}\theta}$ into \mathcal{K} . This map can be extended to a continuous map of $S^{d-\operatorname{rank}\theta}$ into \mathcal{K} .)

The group G deserves the name of gauge group of Yang -Mills theory on \mathbb{R}^d_{θ} if we are working only with gauge fields from $\mathcal{C}' = \mathcal{C}'_m$. This means, in particular, that corresponding functional integral can be taken over \mathcal{C}'/G . (Notice that \mathcal{C}' is a disjoint union of contractible sets, therefore it is easy to analyze the topology of \mathcal{C}'/G using the results above). However, one can show that the group \widetilde{G} consisting of unitary endomorphisms (of elements of $U(\operatorname{Mat}_n(M(A)))$) that transform \mathcal{C}' into itself is larger then G. This follows from the consideration below, but it is possible to show this directly. Namely, if the commutator of unitary endomorphism U with the operator T_k that enters the definition of \mathcal{C}' belongs to Γ^m then $U \subset \widetilde{G}$. It is easy to construct examples of such endomorphisms that don't belong to G, but it is not so easy to give a complete description of \widetilde{G} .

There exists another language that is more convenient to deal with fields gauge trivial at infinity. Let us consider at first the case when the parameter of noncommutativity θ is a non-degenerate matrix. Then the dimension d is even and the algebra $S(\mathbb{R}^d_{\theta})$ is isomorphic to the algebra of integral operators acting on the space $S(\mathbb{R}^p)$ where 2p = d and having a kernel, belonging to $S(\mathbb{R}^d)$. This means that we can consider $S(\mathbb{R}^m)$ as a A-module; we denote this module (Fock module) by \mathcal{F} . The module \mathcal{F} can be considered as a Hilbert module over $A = S(\mathbb{R}^d_{\theta})$. We assume that in the definition of gauge triviality at infinity we have $T \in H\Gamma_1^{0,0}$ and $T^+T = 1$ (i.e. $\Pi' = 0$). Then one can prove that Ker T^+ =Ker TT^+ =Ker $(1 - \Pi)$ =Im Π considered as A-module is isomorphic to \mathcal{F}^r for some $r \geq 0$. (The proof is based on a remark that $\Pi \in S(\mathbb{R}^d_{\theta})$ obeys $\Pi^2 = \Pi$, $\Pi = \Pi^+$, and therefore the corresponding integral operator is a projector on finite-dimensional subspace of $S(\mathbb{R}^p)$.)

Using this fact we construct a map of A^n onto $\mathcal{F}^r \oplus A^n$ transforming $y \in A^n$ into $(\Pi y, T^+ y)$. This map is an isomorphism of A-modules. (The inverse map transforms $(\xi, x) \in \operatorname{Ker} T^+ \oplus A^n$ into $\xi + Tx \in A^n$.)

Notice, that the isomorphism class of the module Ker T^+ depends only on the element of stable homotopy group $\pi_{d-1}(U(\infty))$ determined by T. This remark proves the statement that gauge fields in $\mathcal{C}(T)$ are gauge equivalent to the fields in $\mathcal{C}(T')$ if T and T' determine the same element of $\pi_{d-1}(U(\infty))$ (for the case when θ is non-degenerate).

Every connection on a module $\mathfrak{F}_{rn} = \mathfrak{F}^r \oplus A^n = \operatorname{Ker} T^+ \oplus A^n$ has the form

$$\nabla_{\mu} = \nabla^{st}_{\mu} + \nu_{\mu} \tag{4}$$

where ∇^{st}_{μ} stands for the standard connection $(i(\theta^{-1})_{\alpha\beta}\hat{x}^{\beta},\partial_{\alpha}) = (\Pi\partial_{\mu}\Pi,\partial_{\mu})$ and

$$\nu_{\mu} = \begin{pmatrix} M_{\mu} & N_{\mu} \\ R_{\mu} & S_{\mu} \end{pmatrix}$$
(5)

is an endomorphism of \mathcal{F}_{rn} represented by a block matrix where M_{μ} is an $r \times r$ matrix with entries from \mathbb{C} , N_{μ} is an $r \times n$ matrix with entries from \mathcal{F} , R_{μ} is an $n \times r$ matrix with entries from $\overline{\mathcal{F}}$, and S_{μ} is an $r \times r$ matrix with entries from M(A).

Notice that in the above consideration instead of $A = S(\mathbb{R}^d_{\theta})$ we can consider other algebras; for example, one can take $A = \Gamma^m$ with $m \leq 0$.

Let us consider now a gauge field (3) where $\rho_{\mu} \in \Gamma^m$ (i.e. a gauge field from the class \mathcal{C}_m). Then it is easy to check that the for corresponding gauge field on \mathcal{F}_{rn} we have $S_{\mu} \in \Gamma^m$. (More precisely, S_{μ} has the same behavior at infinity as ρ_{μ} .) This means that instead of gauge fields that belong to the class \mathcal{C}_m^r we can work with the class $\widetilde{\mathcal{C}}_m^r$ consisting of gauge fields on \mathcal{F}_{rn} obeying $S_{\mu} \in \Gamma^m$. (We constructed a one-to-one correspondence between \mathcal{C}_m^r and $\widetilde{\mathcal{C}}_m^r$.)

The gauge group in this formalism should be considered as the group of unitary endomorphisms of \mathcal{F}_{rn} that are represented by matrices of the form

$$\left(\begin{array}{cc}
\mathfrak{M} & \mathfrak{N} \\
\mathfrak{R} & \mathfrak{S}
\end{array}\right)$$
(6)

where $S - 1 \in \Gamma^{m+1}$. Due to the correspondence between \mathbb{C}_m^r and $\widetilde{\mathbb{C}}_m^r$ this group can be considered also as a group of gauge transformations acting on \mathbb{C}_m^r . Imposing conditions $\mathcal{M} = 1$, $\mathcal{N} = \mathcal{R} = 0$, we obtain transformations of \mathbb{C}_m^r belonging to $G = G^{(m+1)}$; if these conditions are not satisfied we obtain gauge transformations of \mathbb{C}_m^r that don't belong to G, but belong to \widetilde{G} . We see that the gauge group is larger than G. However, it is easy to verify, that its topological properties are the same. They coincide with the topological properties of the gauge group considered in Ref. 1.

It seems that the simplest way to work with noncommutative gauge theories on \mathbb{R}^d is to consider unitized algebras. (This is the viewpoint advocated in Ref. 2.) We can reformulate the above consideration working with the algebra Γ^m and corresponding unitized algebra $\tilde{\Gamma}^m$. The gauge fields from $\tilde{\mathcal{C}}_m^r$ are precisely the fields that can be regarded as connections on \mathcal{F}_{rn} , considered as $\tilde{\Gamma}^m$ -module.

Let us consider now the case when the dimension of the space (\mathbb{R}^d) is less than 4. In this case fields of the form $\nabla_{\mu} = \partial_{\mu} + \rho_{\mu}$ where $\rho_{\mu} \in \Gamma^m$ and $m = 1 - \frac{d}{2}$ have finite euclidean action. Let us denote the class of fields of this kind by $\tilde{\mathcal{D}}$. We expect that "almost all" gauge fields having finite euclidean action are gauge equivalent to the fields belonging to \mathcal{D} . It is easy to check that a unitary endomorphism corresponding to a matrix $T \in H\Gamma_1^{0,0}$ transforms \mathcal{D} into itself. The group consisting of endomorphisms of this kind be considered as a gauge group.

Acknowledgments

I am indebted to M. Kontsevich, N. Nekrasov and M. Rieffel for useful remarks.

Appendix

Let us denote by $\Gamma_{\rho}^{m}(\mathbb{R}^{d})$ the class of smooth matrix functions a(z) on \mathbb{R}^{d} obeying

$$\|\partial_{\alpha}a(z)\| \le C_{\alpha} \langle z \rangle^{m-\rho|\alpha|} \tag{7}$$

where $\alpha = (\alpha_1, ..., \alpha_d), |\alpha| = \alpha_1 + ... + \alpha_d, m \in \mathbb{R}, 0 < \rho \le 1, \langle z \rangle = (1 + ||z||^2)^{1/2}.$ We define the star-product of matrix functions using the star-products of their entries and standard rules of matrix multiplication. (The star-product $a \star_{\theta} b$ as always depends on antisymmetric matrix θ .) One can prove that the starproduct of functions $a' \in \Gamma_{\rho}^{m_1}$ and $a'' \in \Gamma_{\rho}^{m_2}$ belongs to $\Gamma_{\rho}^{m_1+m_2}$. (In particular, Γ_{ρ}^m is an algebra if $m \leq 0$.)

A matrix function a(z) belongs to the class $\widetilde{\Gamma}^m_{\rho}(\mathbb{R}^d)$ if

$$\|a(z)\| \le \operatorname{const} \cdot \langle z \rangle^m, \quad \|\partial_\alpha a(z)\| \le C_\alpha \|a(z)\| \langle z \rangle^{-\rho|\alpha|}.$$
(8)

(This condition is stronger than (7).) One says that $a \in H\Gamma_{\rho}^{m,m_0}$ if $a \in \widetilde{\Gamma}_{\rho}^m$ and $a^{-1} \in \widetilde{\Gamma}_{\rho}^{-m_0}$. (We don't assume that a(z) is invertible for all $z \in \mathbb{R}^d$, however, we suppose that $a^{-1}(z)$ exists for sufficiently large ||z||.) One can prove that for every function a(z) from $H\Gamma_{\rho}^{m,m_0}$ and for any θ in the definition of star-product there exists such a function $b(z) \in \Gamma_{\rho}^{-m,-m_0}$ that $1 - a \star_{\theta} b$ and $1 - b \star_{\theta} a$ are matrix functions with entries from $S(\mathbb{R}^d)$.
